MEMORANDUM

TO: Technical Advisory Group City of Fort Lauderdale

FROM: V. P. Amy, Geraghty & Miller, Inc.

RE:

Intermediate Casing Point, Test-Injection Well, City of Fort Lauderdale, Ft. Lauderdale, Florida

Attached is our report on the recommendation regarding the change in the setting point for the 34-inch casing in the test-injection well.

This recommendation is made in an effort to prevent the occurrence of a future problem. Setting the 34-inch casing some 70 feet shallower will not compromise its intended purpose and should aid in preventing a problem. We will keep you advised of the results of the gyroscopic surveys and other events as they occur.

### INTERMEDIATE CASING POINT TEST-INJECTION WELL CITY OF FORT LAUDERDALE FORT LAUDERDALE, FLORIDA

At the March 5, 1981, meeting with the Technical Advisory Group, the results of the pilot hole drilling, logging, and testing were discussed and recommendations presented regarding the setting points for the outer (34-inch) and inner (24inch) casings. It was recommended that the 34-inch casing be set at 1970 feet for the reasons listed below.

Dolomite and limestone occur in the interval between approximately 2000 and 2100 feet. The upper contact between this unit and the overlying limestone is gradual and is marked by the appearance of dolomite interbedded with the limestone, grading into dolomite. The dolomite is indicated on the induction log by the presence of high resistivity. Also, because it is comparatively hard, it does not wash out during drilling, so that it shows as a pronounced "gauge-size" (or nearly so) hole on the caliper log.

When this section was drilled, a cavity was encountered at  $\pm 2096$  feet. Examination of the caliper log reveals that some over-size portions are present in the dolomite; these may be due to fractured rock which fell in or was drilled out, giving the hole a rugose appearance on the caliper log. The television survey, which was performed while the well was being pumped, revealed that flow was entering the borehole at 2075 feet (that depth is based on the camera odometer and may be in error).

The specifications originally called for a setting point of 2000 feet for the 34-inch casing to seal off water containing less than 10,000 mgl of total dissolved solids. That point was selected based on the reasonable assumption that salt water (35,000 mgl TDS) is present at this depth.

At the March 5 meeting, it was recommended and accepted by the Group that a setting of  $\pm 1970$  feet be used. This depth rather than a deeper one was selected to prevent the possible loss of cement around the base of the casing because of the nature of the dolomite. At that point, 1970 feet, the base of the casing would be set in a fine- to medium-grained, chalky limestone. This would also permit the cement plug called for in the specifications to be set at the top of the dolomite or in the interbedded limestone and dolomite to effect a seal and prevent cement loss.

Following the meeting, the Contractor proceeded to ream the hole to ±1970 feet and prepare for setting the 34-inch casing. During the reaming operations, directional surveys were made by the Contractor at the prescribed intervals. After each survey was made, the film was analyzed and the position of the hole was calculated by the minimum curvature method. Surveys also were performed during the drilling of the pilot hole so that the relative positions of the reamed and pilot holes could be monitored as the work progressed.

Comparison of the survey data reveals that the plotted position of the centers of the holes deviate from each other, with the reamed hole plot showing a greater overall inclination from the vertical than the pilot hole surveys. As a consequence, the plotted position of the ream appears to be further from the common reference point for the surveys (the base of the 42-inch casing at 950 feet). This departure can be first seen in the surveys at 1188 and 1189 feet, and becomes more apparent with increasing depth.

The distances between the survey points below 1700 feet are listed in the following table. Copies of the survey data and plots showing the relationships between position are attached.

Survey	Depth	Distance
Reamed Hole	Pilot Hole	(ft)
1702	1692	2.4
1772	1754	2.55
1838	1816	2.85
1901	1878	2.90
1934	1941	2.80

Much of the pilot hole is overgauge because of the nature of the limestone. Below 1700 feet, the diameter is 18 to 20 inches, with the exception of the interval below 1950 feet where the diameter reduces somewhat (to 15 inches) owing to Geraghty & Miller, Inc.

the presence of the interbedded limestone and dolomite. The reamed portion of the hole is in excess of 57 inches in diameter (the limit of the Schlumberger caliper tool). Consequently, the plotted positions of the holes overlap so that effective communication exists.

As noted previously, the reamed portion of the hole is further from the vertical than the pilot hole. Thus, the position of the pilot hole is located on the low side of the reamed hole. According to the survey data, this relationship is quite consistent. If the 34-inch casing is set and centralized at 1970 feet, this would offset the position of the center of the next reaming (nominal 34-inch-diameter) relative to the pilot hole, based on the survey data. This would raise the possibility that the next reaming may depart from the track of the pilot hole.

To avoid this possibility, it is recommended that a shallower casing setting be employed. This would permit the stage bit used for the next ream to re-enter a previously drilled section of hole rather than drilling new hole at the outset, and should allow the bit to track the low side of the hole and stay on the course of the pilot hole.

Review of the data indicates that a setting of approximately 1900 feet (proposed by the Contractor) should bring the casing back to a point that would allow the ream bit to re-enter the "old ream" hole, giving the tool string the flexibility to seek the original path of the pilot hole. Preferably, the casing would not be centralized at the bottom to permit it to be in as close contact to the "low side" of the reamed hole, placing it as close to the plotted position of the pilot hole, as possible. Examination of the caliper log reveals that most of the reamed hole is well in excess of 40 inches in diameter (the approximate diameter of the centralizers). Furthermore, the hole is reasonably straight (about 7 feet off center in about 1000 feet) so that centralizers placed further up the casing would tend to provide stand-off. That, coupled with the larger diameter of the hole, should be more than enough to provide an adequate sheath of cement around the casing. Also. the 24-inch casing will be set inside the 34-inch pipe and cemented, thereby providing additional protection, so that it is not absolutely critical to centralize the 34-inch casing.

The procedure that the Contractor plans to follow will consist of installing the 34-inch casing to approximately 1900 feet (pad datum). He will install the tool string in the hole with a 32-inch bit attached to provide centralization, and then perform a gyroscopic survey of the casing to relate its position to the plotted position of the pilot hole. The hole will then be sounded and back-filled with crushed rock or some other suitable material and a cement plug (about 10 feet thick) set on top of the gravel. The top of the cement plug will be left below the bottom of the casing. The 34-inch casing will be cemented in place. After cementing, the plug and gravel will be drilled out slowly; directional surveys will be run at 30-foot intervals in order to check the hole position. This procedure will be followed until the Contractor has provided reasonable assurance that the reaming is tracking the pilot hole.

Setting the casing at the 1900-foot depth will not compromise the well's construction, as the casing will still be seated in the same type of material as that found at 1970 feet. Also, water containing less than 10,000 mgl of TDS still will be protected as the casing still will be seated below the point where water of this quality occurs. A copy of the analysis of a water sample collected after 48 hours of pumping during the Floridan aquifer test (hole open from 950 to 1500 feet) It shows that the water produced from this zone is attached. (or zones) contains water with 13,038 mgl of TDS.

Review of the records indicates no unusual problems associated with performing the various surveys. The data indicate a departure in the track of the two holes. In the bottom 100 feet or so, the amount of departure has remained about the same. That, combined with the over-size nature of both the pilot and reamed holes indicates that no problem exists now. The fact that the tracks are parallel to each other suggests that the lead bit is tracking the pilot hole and possibly that much of the departure is "apparent" due to inherent instrument error. In any event, prudence dictates that measures be taken now, when the opportunity exists, to avoid a potential future problem.

> Respectfully submitted, GERAGHTY & MILLER, INC.

Vincent P. Amy
