CRAIG A SMITH & ASSOCIATES

CONSULTING ENGINEERS • PLANNERS • SURVEYORS

June 24, 1997

Ms. Heidi Vandor, P.G. Florida Department of Environmental Protection Southeast District P.O. Box 15425 West Palm Beach, FL 33416

RE: REPERMITTING THE OPERATION OF THE CITY OF PAHOKEE

INJECTION WELL

CAS PROJECT NO. 94-0404

Dear Ms. Vandor:

We are transmitting additional information on the Pahokee Injection Well. These are intended to complement the repermit application submitted earlier.

The following are attached:

- 1. Location Maps
- 2. Details of Wells
- 3. Updated Area Review and Evaluation
- 4. Wastestream Analysis
- 5. Process Description
- 6. Mechanical Integrity Test Results
- 7. Groundwater Monitoring Data
- 8. Specific Injectivity Data
- 9. Financial Responsibility Regarding Plugging and Abandoning Data
- 10. Meter Certification
- 11. Additional Wastestream Analysis
- Certifications.

Please let us know if you need additional information.

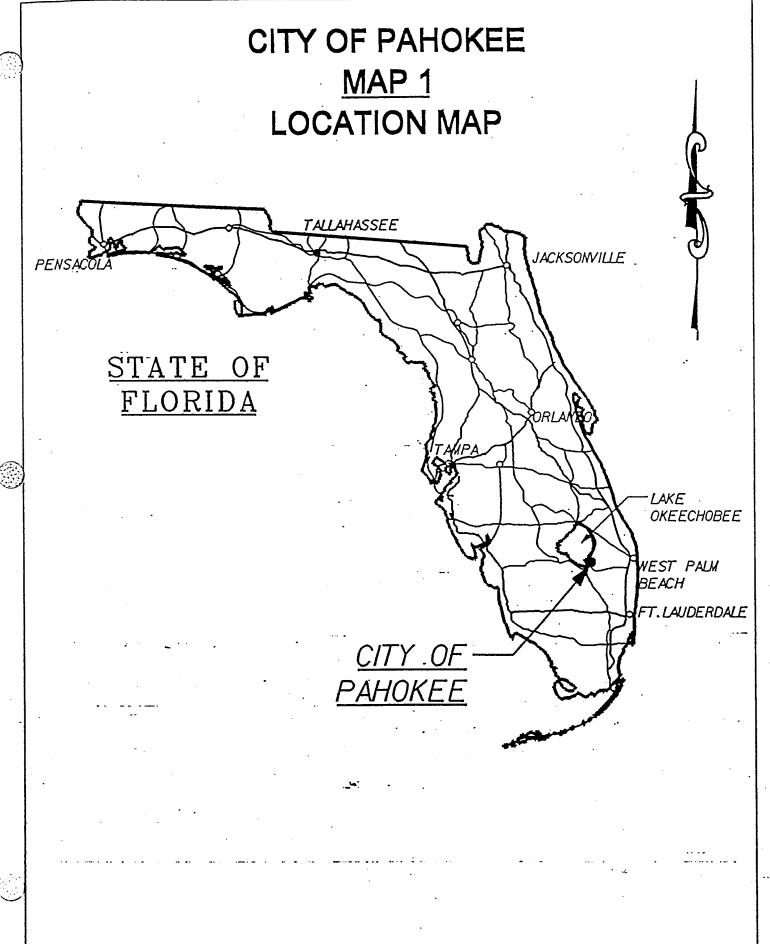

Sincerely,

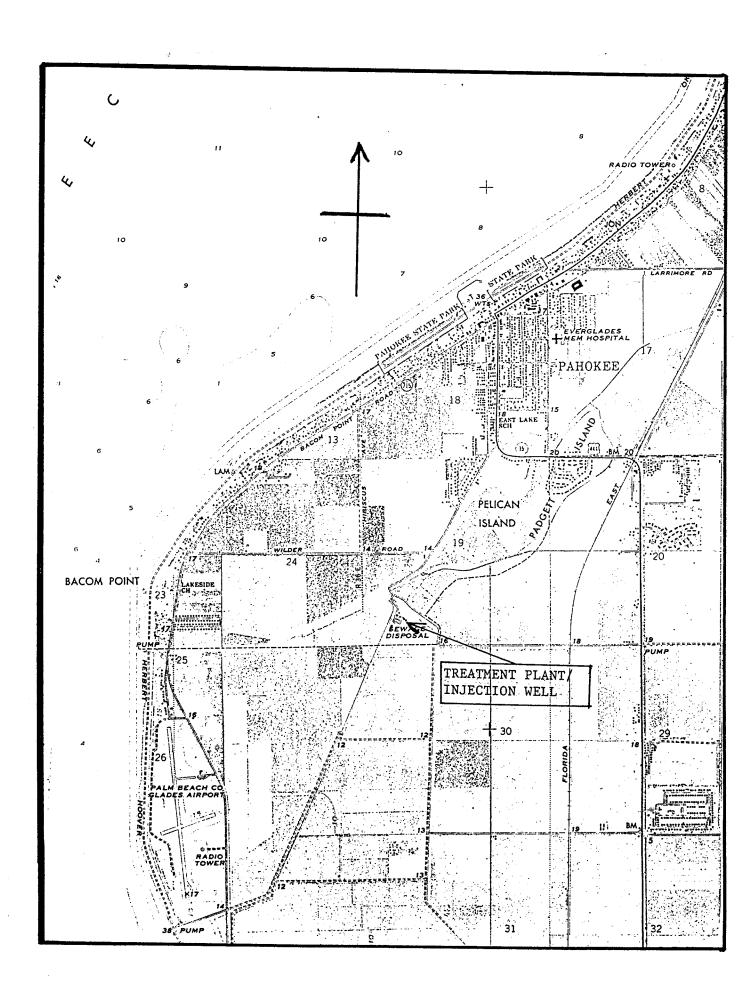

CRAIG A. SMITH & ASSOCIATES

Robert Binger, P.E. Project Manager

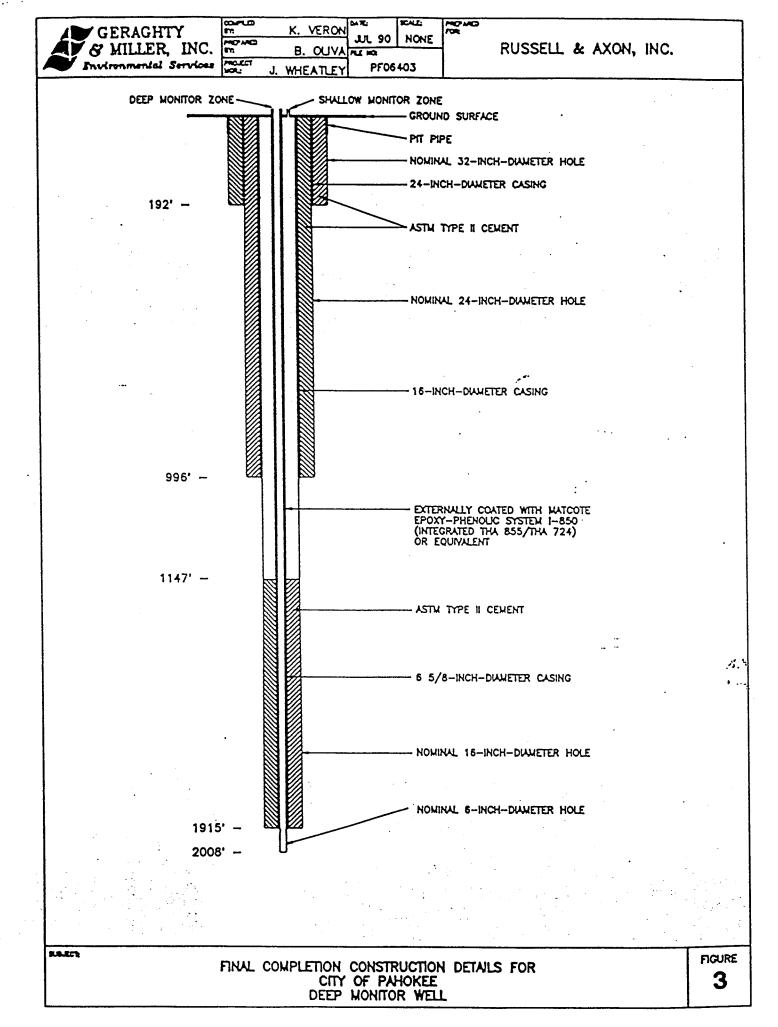

i:\munic\97-404\001.doc

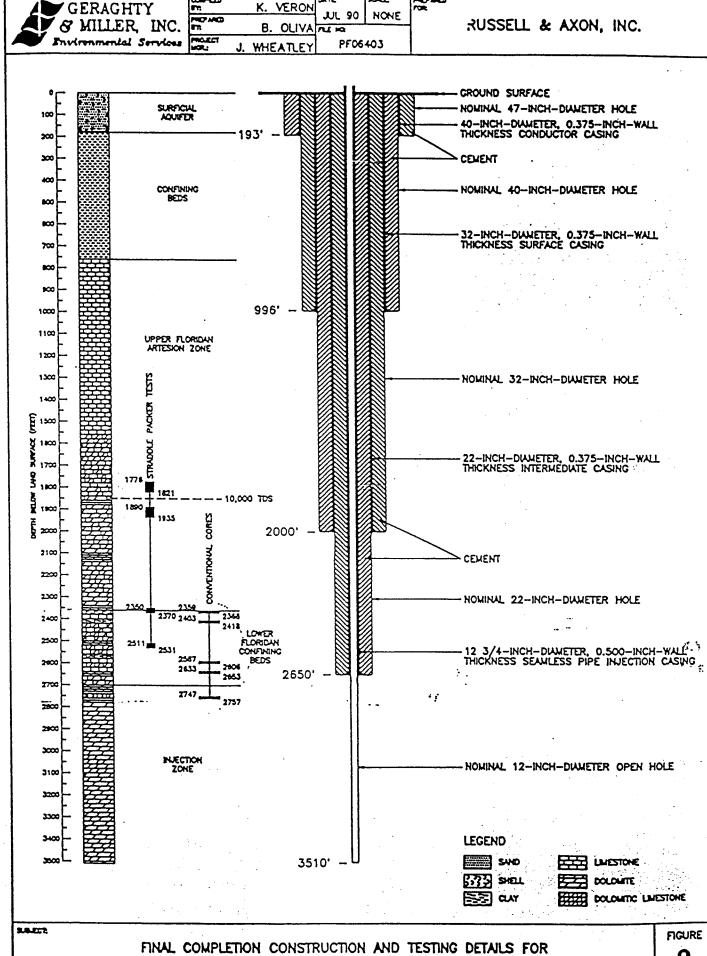

ATTACHMENT 1: Location Map

ATTACHMENT 2: Details Of Wells

ATTACHMENT 3: Evaluation And Review Of Area And Updated Review Information

June 24, 1996 PF0782.001

Re:

Operating Permit Application Support

City of Pahokee Class I Injection Well System Operating Permit Renewal

CAS Project No. 93-1599

Dear Mr. Binger:

Enclosed please find one original copy of the narrative evaluation of the size of the area of review, based upon the available operation and monitoring data, with a justification for the selected radius. Also included are updated hydrogeologic information for the area of review, the updated Area of Review Map, the final construction details for the City of Pahokee Injection Well (Figure 2), the final construction details for the City of Pahokee Deep Monitor Well (Figure 3), and water-level elevation contour maps both for the Surficial Aquifer (Figure 4) and Floridan Aquifer (Figure 5). A Site Plan for the City of Pahokee Wastewater Treatment Plant also is included for your use. The text for the narrative evaluation and the hydrogeologic information (Microsoft WORD 6.0), with the 3 CADD (Release 12) generated figures (the Site Plan and Figures 2 and 3), are included on the enclosed diskette.

We appreciate the opportunity to provide professional services to Craig A. Smith & Associates in support of the Operating Permit renewal application for the City of Pahokee Injection Well System. If you have any questions or comments, please feel free to contact us.

Sincerely,

GERAGHTY & MILLER, INC.

UPDATED AREA OF REVIEW

The minimum radius for the area of review is one mile, as defined in Section 62-528.300 (4), Florida Administrative Code (FAC); that radius has been utilized for the updated City of Pahokee Injection Well System area of review, based on 1) the original area of review radius of one mile utilized for the permit application to construct and test the injection well system, and 2) an evaluation of the available injection-well system operation and monitoring data. The size of the area of review originally was based on a conservative estimate of the width of the "zone of endangering influence" in the vicinity of the injection well. The area of review represents the estimated land surface area overlying and encompassing the lateral area in which the buoyant forces or increased pressures in the injection zone may cause the migration of the injected or formation fluid into an underground source of drinking water.

Operation and Monitoring Data

The operational injection pressure and injection flow volume data collected between January 1992 and November 1996 has been presented in both tabular and graphical form in order to evaluate the operational efficiency (performance) of the well during the 5-year period and to justify the size of the selected area of review.

The performance of an injection well is based on 2 main factors which influence the wellhead operating pressures over the life of the well. The first is the ability of the receiving ("Boulder Zone") formation to accept the effluent at design capacities. The second factor influencing the wellhead operating pressures over time is the condition of the injection casing, which is responsible for the friction loss component of the total wellhead pressure measured at the surface. The performance of an injection casing changes over time as the casing "ages" and, in general, varies with the roughness coefficient (C) of the casing (as estimated by the modified Hazen-Williams equation). An increasing trend in wellhead injection pressure (per unit volume of injected effluent) over time is attributed to one of these factors.

An evaluation of the available operational data from the City of Pahokee Injection Well, System indicates that the average daily flow (wastewater injection rate) volume has varied between 0.84 million gallons per day (mgd) and 1.74 mgd for the months of January 1992 through December 1996. The average daily operating wellhead pressure has varied between 35 pounds per square inch (psi) and 49 psi for the months of January 1992 through December 1996. Based on the injection pressure and injection flow volume data collected from January 1992 to November 1996 (Figure #), it appears that the injection well efficiency has not significantly decreased since January 1992. The (monthly-average) maximum daily flow rate for the 23-inch inside diameter injection well was 2.62 mgd (less than 2000 gallons per minute [gpm]), equivalent to a downhole velocity of less than 5.4 feet per second within the well casing, between January 1992 and November 1996. During that same period, the peak hourly flow rate to the injection well did not exceed 3.2 mgd (less than 2250 gpm) or approximately 6.6 feet per second.

The monthly maximum and monthly minimum pressure readings from the dual-zone Deep Monitor Well, from both the upper monitoring zone and the lower monitoring zone (measured in psi at the wellhead), have been presented both in graphical and tabular form. Readings collected between January 1992 and March 1993, appear to be anomalous. However, according to the current Lead Operator at the City of Pahokee Wastewater Treatment Plant, between January 1992 and March 1993, monitoring zone pressure readings were recorded while the monitoring zone pumps were operating (in order to purge water for the monthly water sampling event). Since March 1993, the pumps for the wells have not been used and the monitoring well zones are allowed to flow under artesian conditions prior to each monthly sampling event. Since March 1993, daily monitoring zone pressure readings have been recorded while the well zones were shut-in. Based on the available lower monitoring zone pressure data collected from March 1993 through November 1996, the lower monitoring zone pressure readings appear stable, ranging from a minimum of 12 psi to a maximum of 20 psi. Total dissolved solids concentrations analyzed from lower monitor zone water samples were reported between 16,000 and 18,600 milligrams per liter during the 5-year period and do not demonstrate either an increasing or decreasing trend during the period from January 1992 to November 1996.

A review of the testing results submitted with the March 1991 Geraghty & Miller report entitled "Construction and Testing of Injection Well System #1, City of Pahokee Wastewater Treatment Plant, Palm Beach County, Florida" and the available operation and monitoring data collected during the active life of the injection well system indicate that the injection zone is capable of accepting treated effluent at the permitted rate (3.9 mgd). The operation and monitoring data do not provide evidence that injection of treated wastewater into the "injection zone", located below a depth of approximately 2650 feet, has caused upward migration of injected or formation water into an Underground Source of Drinking Water.

Updated Area of Review Map

An updated Area of Review Map is presented as Figure 1, illustrating the one-mile area of review radius. The updated locations of surface-water bodies, roads, and residences have been included by utilizing the most recent U.S. Geological Survey topographic map available (1970), the most recent (1995) aerial photographs of the vicinity and the most recent (available) City of Pahokee street atlas. South Florida Water Management District (District) well permit postings were reviewed to update the current location and construction data for permitted water supply wells within a one mile radius of the City of Pahokee Injection Well System. The District records indicated that no potable water supply (public or private) or irrigation water supply wells are located (posted as permitted wells at the District) within a one mile radius of the City of Pahokee Wastewater Treatment Plant (Figure 1). The final completion construction and testing details for the City of Pahokee Injection Well and Deep Monitor Well are presented as Figures 2 and 3, respectively. The Palm Beach County Health Department (formerly part of the Palm Beach County Department of Health and Rehabilitative Services), a state agency, was contacted to determine whether a record of permitted private water supply wells exists for property owners (permittees) within the area of review. According to Mr. Russ Weaver with that

agency, listings of permittees for Palm Beach County are archived at that Department, but the permit listings are indexed chronologically and are not available in an electronic format (or cross-referenced by the well location). In addition, the status of the permits are not updated.

The Florida Geological Survey (formerly the Florida Bureau of Geology) Division of Oil and Gas was contacted to determine if any former or current oil (or gas) wells exist in the area of review. According to Mr. Edward Garrett with that agency, records indicate that no abandoned or active oil or gas (either exploratory or production) wells exist within 3 miles of the area of review.

Based on the available operation and monitoring data for the injection well system, the one mile area of review radius appears to be a conservatively large estimate of the potential width of the "zone of endangering influence" in the vicinity of the injection well. However, due to the relative scarcity of available well data within that one mile radius, and based on Section 62-528.300 (4) (b), FAC, the originally permitted width of the area of review was retained for the purpose of updating regional hydrogeologic data in the vicinity of the Pahokee Injection Well System.

UPDATED GEOLOGIC AND HYDROGEOLOGIC INFORMATION

Local and regional geologic and hydrogeologic information was presented in the March 1991 Geraghty & Miller report entitled "Construction and Testing of Injection Well System #1, City of Pahokee Wastewater Treatment Plant, Palm Beach County, Florida". A brief review of the regional hydrogeologic setting for the vicinity of the injection well system follows to indicate the general vertical and lateral limits within the area of review of all underground sources of drinking water, their position relative to the injection formation and the direction of water movement, where known, in each underground source of drinking water which may be affected by the proposed injection.

The lithologies encountered during the drilling of the pilot hole for the City of Pahokee injection well are presented as a stratigraphic column on Figure 2 with corresponding hydrogeologic units defined to the right of the column. The uppermost 180 feet of sediments encountered during pilot hole drilling were Pleistocene, Pliocene, and late Miocene-age sands, in addition to silts, limestone and shell. These sediments contain the Surficial Aquifer which is used as a major source of drinking water throughout most of Palm Beach County. Due to the presence of highly mineralized water in the Surficial Aquifer in western Palm Beach County, the City of Pahokee uses water from Lake Okeechobee for drinking water and irrigation purposes.

The altitude of the water table in the Surficial Aquifer in April 1984 (after 1988 USGS-Water Resources Investigations Report 88-4056, modified from Miller, 1985a.) is presented as Figure 4. The water table is shown at an elevation of between 8 and 10 feet (based on the National Geodetic Vertical Datum [NGVD] adjustment of 1929) in the vicinity of the Pahokee Injection Well System. Based upon a review of the 1970 U.S. Geological Survey topographic map, the land surface elevation shows little slope in the area of review and appears to be between approximately 10 and 15 feet NGVD. Within the area of review, the groundwater flow direction in the Surficial Aquifer appears to be away from the higher elevations at the Lake Okeechobee shoreline. The shallow groundwater also appears to flow from the lake's primary canals toward groundwater depressions between the canals to the east of the lake (Figure 4).

Underlying the Surficial Aquifer are approximately 600 feet of Miocene clay and marl which form a confining sequence between the Surficial Aquifer and the lower Miocene (and Oligocene) to Eocene limestones and dolomites of the Floridan Aquifer. These sediments form a confining sequence referred to as the Hawthorn Group.

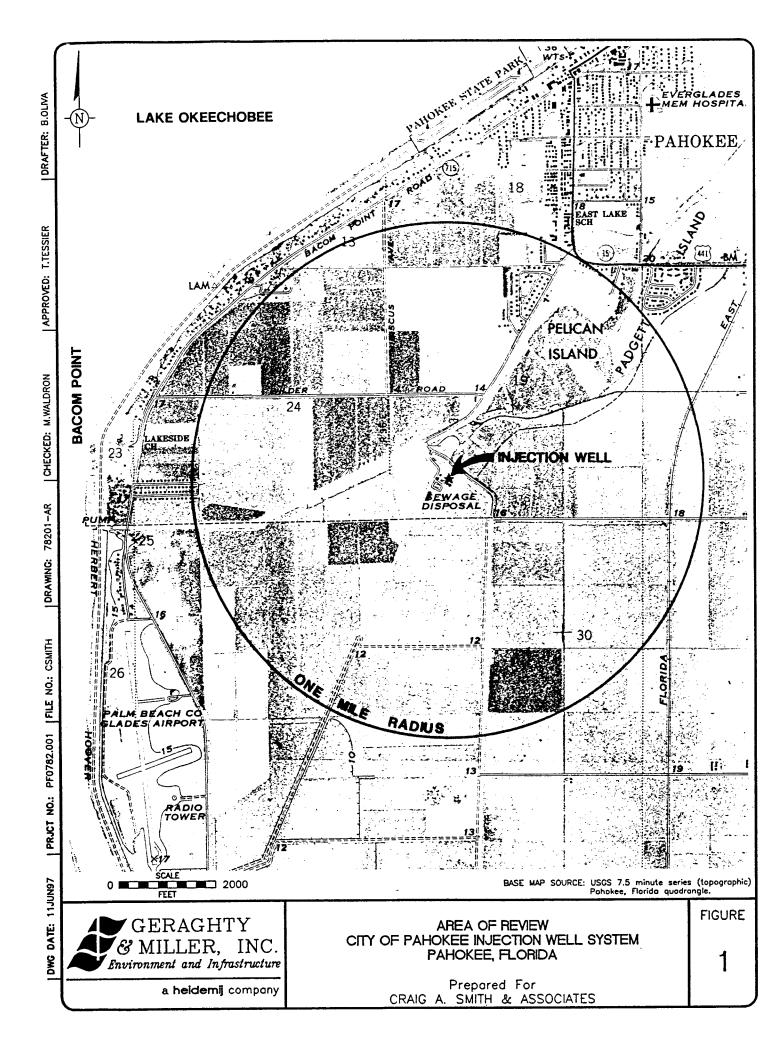

The Hawthorn Group sediments overlie the Floridan Aquifer which exists under artesian conditions with a potentiometric level above land surface. The dense Miocene clays of the overlying Hawthorn Group sediments provide good confinement for this aquifer. From approximately 780 to 910 feet deep, the limestones correspond to descriptions of the Suwanee and Tampa Formations and to the Ocala Group limestones. The middle to upper Eocene limestones, dolomitic limestones and dolomites of the Avon Park and Lake City Limestone Formations were encountered between 910 and

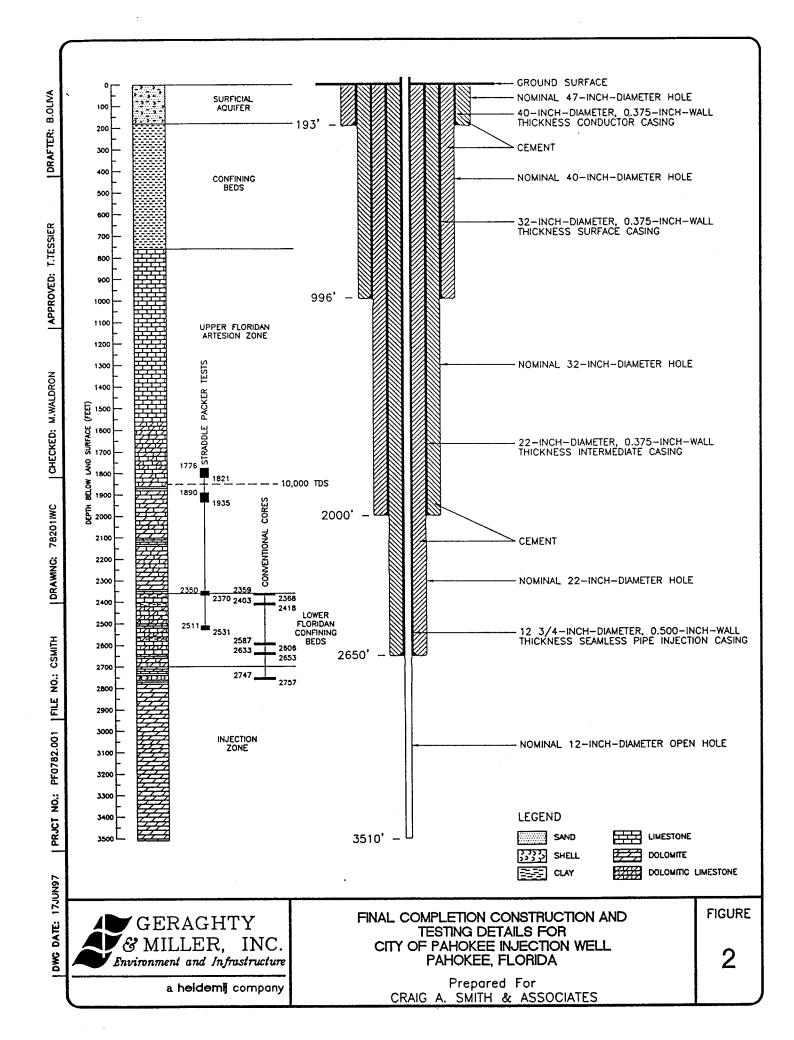

2090 feet. The limestones and dolomites comprise the Upper Floridan Aquifer. The existence of the Lake City limestone in this area was inferred from the literature as there was insufficient microfossil evidence in samples from this pilot hole to delineate a base for the Avon Park Formation. Dolomite was first encountered at 1560 feet deep. Below 2090 feet, the lower Avon Park or Lake City Limestone Formation consists of interbedded limestones and dolomites. Based on the testing program, a confining sequence underlying the Upper Floridan Aquifer was defined between a depth of approximately 2350 and 2650 feet at the City of Pahokee injection well. This confining sequence, also referred to as the "Lower Floridan Confining Beds" (Figure 2), overlies a section of highly permeable dolomite referred to as the "Boulder Zone".

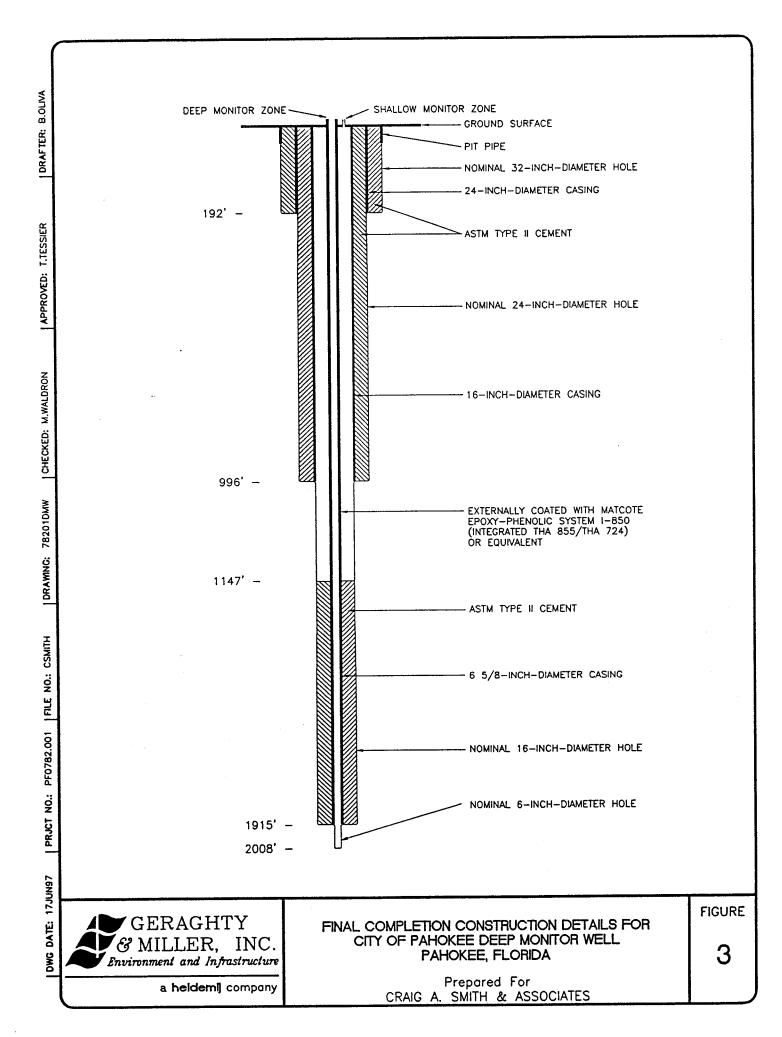

The potentiometric surface elevation contours (in feet, referenced to NGVD) and the generalized groundwater flow directions for the artesian Upper Floridan Aquifer in May 1980 are presented as Figure 5 (revised from Johnston and others [1981], and Healy [1982]). The potentiometric surface sloped gently toward the east in the area of review. Water quality in the Floridan Aquifer is poor in comparison to Surficial Aquifer water quality. Water from the Floridan Aquifer in this area contains concentrations of dissolved solids which exceed drinking water standards. The aquifer is not extensively utilized as a source of drinking water in Palm Beach County because of the additional treatment required to meet drinking water standards. During construction and testing of the injection well, representative water samples were collected from isolated sections of the injection well pilot hole during straddle-packer pumping tests and from the proposed injection zone. Water samples were analyzed for selected ions to establish the 10,000 milligrams per liter (mg/L), total dissolved solids (TDS) concentration interface (the depth below which the TDS concentration exceeds 10,000 mg/L). As reported in the March 1991 Geraghty & Miller report, the 10,000 mg/L TDS interface occurs at a depth of approximately 1820 to 1890 feet in the Upper Floridan Aquifer.

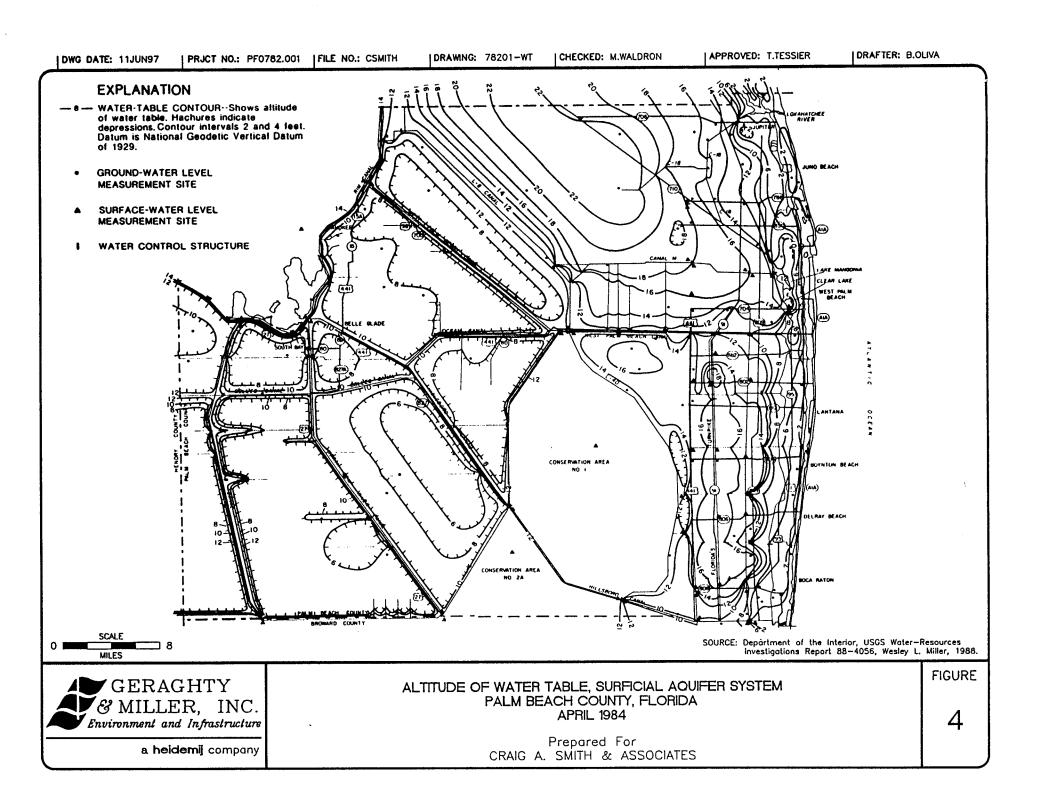

The top of the lower Eocene sediments of the Oldsmar Formation were first encountered at a depth of approximately 2700 feet as characterized by the vuggy texture of the dolomite drill cutting samples and large scale dissolution features noted on a caliper log. This zone contains highly mineralized water and is used throughout south Florida for the disposal of wastewater.

PAHOKEE WASTEWATER TREATMENT PLANT INFLUENT/EFFLUENT CONCENTRATION FOR 1996

ATTACHMENT 5: PROCESS DESCRIPTION

CITY OF PAHOKEE - REPERMITTING OF INJECTION WELL

Process Description

The Pahokee Wastewater Treatment Plant was initially constructed and placed in operation in the mid sixties. The design capacity of this first train is 0.50 MGD. A second "Walker Modular" train was added in 1974 with 0.70 MGD design capacity. The current permitted capacity is 1.20 MGD based on a three month average daily flow.

The average inflow to the Pahokee Wastewater Treatment Plant for 1996 was 0.948 MGD or 658 gpm. The corresponding average inflows for 1994 and 1995 were 1.160 MGD and 1.137 MGD respectively.

The annual average of maximum and peak inflow rates for 1996 are 1.10 MGD and 2.02 MGD respectively. The plants inlet pipes are 12 inches and 8 inches. There is a third 4 inch inlet pipe from the treatment plant pumping station. The influent discharges at elevation 26.75 ft. (approximately 11 feet above ground level) to a mechanical bar screen. There is also a manual bar screen which operates when the mechanical screen is not operating. The total influent flows to the splitter box from the bar screen.

The splitter box is adjustable to permit sixty percent (60%) of the flow to be treated by the Walker Modular Plant (Train #2) and forty percent (40%) by Train #1.

The influent and effluent CBOD and TSS concentration for 1996 are shown at Attachment 2. The CBOD ranges from 208 mg/l on December 3 to 69 mg/l on 23 July. The TSS varied from 250 on December 3 to 61 mg/l on July 2. The average CBOD and TSS for the year were 134.5 mg/l and 124.25 mg/l respectively. The annual average CBOD and TSS of the effluent from the primary clarifier were 57.28 mg/l and 59.07 mg/l respectively. The average percentage removal of CBOD and TSS achieved in the primary clarifier is 68 percent and 52 percent respectively. These results are summarized below:

	CBOD	TSS
Influent Max - December 3, 1996	208 mg/l	250 mg/l
Influent Min - July 23, 1996	69 mg/l	61 mg/l
Average for 1996	134.5 mg/l	124.25 mg/l
Average Influent from Primary Clarifier	57.28 mg/l	59.07 mg/l
Average Removal Primary Clarifier	68%	52%
Average Effluent 1994 - 1996	4.21 mg/l	627 mg/l

<u>Train #1</u>: The forty percent flow from the splitter box is gravity fed to the primary clarifier which also acts as a grit remover. The average $CBOD_5$ and TSS of the effluent leaving the primary clarifier to the aeration tanks are 57.28 mg/l and 59.07 mg/l respectively. There are two (2) equal compartments to the aeration tank and each

volume is 9,597 ft³ and total volume is 19,195 ft³. Flow through the aeration tanks is in series.

The flow from the aeration tank is conveyed by a 16 inch pipe to a splitter box which permits equal flow to each of two 5841 cu. ft. secondary clarifiers. The effluent from these clarifiers is mixed with the effluent from Train #2, flows to a holding tank and is subsequently pumped to the injection well on the site. The average CBOD $_5$ and TSS of the dry weather effluent from 1994 to 1996 are 4.21 mg/l and 6.27 mg/l respectively. The return sludge is taken from the secondary clarifier and pumped to the inlet of the aerators.

Sludge from the primary and secondary clarifiers are pumped to the aerobic digester. The wasted sludge is gravity fed from the digester tank to the sludge drying beds.

<u>Train #2</u>: (Walker Modular Plant). The Walker Modular Plant treats approximately sixty percent (60%) or approximately 0.52 MGD of the plant inflow. The Walker Modular Plant is a large circular tank with diameter 72.5 feet. The respective volumes of the aeration tanks and the aerobic digester are 16,245 cu ft and 22,950 cu ft. The average $CBOD_5$ and TSS of the influent to the Walker Plant in 1996 are 134.5 mg/l and 124.25 mg/l respectively.

Return sludge is airlifted from the clarifier to the aeration compartment. Waste sludge from the aerobic digesters is gravity fed to the adjacent sludge drying beds. The effluent is mixed with the effluent from Train #1 and flows to the holding tank and then pumped to the injection well. The pumping rate and pressure at the injection well are 900 gpm and 38 psi respectively.

A schematic of the treatment plant is shown at Attachment 1.

Summary

Permitted capacity: 1.2 MGD based on three months average.

Date placed in service (in the current capacity): 1974

Modification in last five years: None

Injection Well Mechanical Integrity Testing City Of Pahokee

Introduction

In fulfillment of Section 17-28.250(1)(c), Florida Administrative Code (FAC), the City of Pahokee injection well has been tested for mechanical integrity. This report describes the testing methods that were performed, the results of the testing, and provides interpretation of the data collected during the 5-year Mechanical Integrity Test and the monitoring data since the last testing. As specified in section 17-28.130(6) FAC, the mechanical integrity test consisted of a hydrostatic pressure test of the injection casing, a temperature log, a Radioactive Tracer Survey (RTS) and a television survey.

Hydrostatic Pressure Test

On June 21, 1994, an inflatable packer was set near the base of the 12 3/4-inch injection casing at a depth of 2645 feet below pad level the base of the injection casing is 2650 feet below pad level. The packer, which measured 10 feet long, was inflated and the casing was internally pressurized to 147 pounds per square inch (psi). A pressure decline of 2 psi was then observed over a sixty minute test period. This decline represents a 1.4 percent change in the original pressure, which is within the 5 percent limits specified by the regulations. A copy of the test gauge inspection certification records and certified results of the hydrostatic pressure test are contained in Appendix A This test was witnessed by James A. Wheatley P. G., of Water Technology Associates, Inc. and David McNabb P. G., from the Florida Department of Environmental Protection.

Temperature Log

On June 22, 1994 Florida Geophysical Logging, Inc. conducted a temperature log on the injection well from the surface to a total depth of 2787 feet below pad level. The temperature was a constant 83.5 degrees from surface to 2650 feet below pad level (casing shoe) below this point the temperature increases to 85 degrees to a depth of 2734 feet. The temperature in the open hole from 2734 to the bottom of the logged interval then remained constant at 84.25 degrees. A copy of the temperature log is contained in Appendix B.

Radioactive Tracer Survey

On June 22, 1994, a Radioactive Tracer Survey (RTS) was conducted. A detailed description and interpretation of the Radioactive Tracer Survey is presented in the following text. The test began with Florida Geophysical Logging, Inc., conducting a background Gamma Ray Log (GRL) and a casing collar locator (CCL). The background GRL was "memorized" and subsequently reprinted on each "out of position" logging run to serve as a means of comparison. A schematic diagram of the logging tool is represented at the top of the Radioactive Tracer Survey Log. Each logging run is identified by a file number presented at the top and bottom of the log, an example is the background log PIWRTS1. After the completion of the background Gamma Ray Log the logging tool ejector was calibrated to a 0.5 millicurie (MCI) per second discharge, and the reservoir was loaded with 10 millicuries radioactive Iodine 131. A copy of the Radioactive Tracer Survey is contained in Appendix C.

The first test conducted was a static test (PIWRTS3). For this test the ejector port was positioned 1 foot below the bottom of the 12 3/4 inch injection casing and one MCI of tracer material was released under static conditions (no injection occurring). Time drive monitoring was conducted for 67 minutes after release. At about the one minute mark, the middle detector (located 1.5 feet above the ejector) shows evidence of the slug dispersing upward from the ejector. Readings increase from background values of approximately 20 gamma ray American Petroleum Institute (GAPI) units to about 2000 GAPI units within a one minute period. Readings from the bottom detector, located 8.5 feet below the ejector, increase from the background of approximately 20 GAPI units at about the 7 minute mark to a maximum of approximately 1080 GAPI units about 17 minutes after tracer ejection. These results indicate that the slug was dispersing at a rate less than one foot per minute. After the 67 minutes of time drive logging the tools were moved up hole and logged out of position (PIWRTS4). The results of this log indicate that the tracer material had dispersed to a point approximately 45 feet above the point of ejection. The injection casing was then flushed approximately 2100 gallons of water (plant effluent). Following the flushing an out of position log was conducted (PIWRTS5) from below the casing to 2360 feet below land surface (bls) this log shows that all tracer material had been flushed out of the casing because all gamma ray levels returned to background levels. These results are interpreted as providing evidence that the casing integrity is sound and there are no channels behind the casing.

For the next test (low rate test) an injection rate of 29 gallons per minute (gpm) was established using plant effluent. The tracer ejector was positioned 5 feet above the bottom of the casing the recorder was placed in the time drive mode (PIWRTS6) and a 1.5 MCU slug of tracer material was ejected. The readings from the middle gamma ray detector began to increase from background within seconds of ejection and returned

to background after about 30 minutes later. The readings from the bottom detector increased from background approximately 2 minutes after ejection. No detection of the tracer material was seen at the upper gamma ray detector any time during 60 minutes of time drive monitoring. The tools were then logged out of position (PIWRTS7) to a depth of 2400 feet bls. No indication of movement up hole of the tracer material was observed. These results are interpreted as providing evidence that the casing integrity is sound and there are no channels behind the casing.

The final tracer test was the high rate test. The injection into the well was adjusted to a rate of 500 gpm, the logging tools were positioned so that the ejector was 1 foot below the bottom of the casing, the recorder was placed in time drive mode (PIWRST8) and 7.5 MCI of tracer material was ejected. Increases in gamma ray detection were seen almost immediately on both the middle and bottom gamma ray detectors. Gamma ray levels returned to background levels in approximately 1.5 minutes after tracer ejection. No indication of tracer material was seen by the upper gamma ray detector. Observation and recording of the data continued for 60 minutes. The tools were then logged out of position (PIWRTS9) to a depth of 2400 feet bls. No indication of movement up hole of the tracer material was observed. These results are interpreted as providing evidence that the casing integrity is sound and there are no channels behind the casing.

Upon the completion of all the above mentioned tests a final background log was conducted (PIWRTS10) on the total depth of the well. The logs were recorded over traces of the initial background log and showed excellent repeatability except for approximately 10 feet around the base of the injection casing attributed to staining during tracer material ejection.

Television Survey

Copies of the television survey are included with this report for your review (Appendix D). Florida Geophysical Logging, Inc., performed the logging on June 23, 1994. The survey was performed from land surface (pad level) to a depth of 2750 feet bls, where visibility declined rapidly. Water clarity above this elevation was good, enabling the camera to capture clear images of the casing interior, casing seat, and open-hole section. The survey did not reveal any substantial deterioration of the casing.

Monitoring Well Data

The City of Pahokee has performed analyses on water samples obtained from the deep and shallow zones of it's duel zone monitor well on a weekly schedule for the following perimeters; temperature, pH, conductivity, chlorides, TDS and ammonia. During the first 12 to 18 months many of the data sets show various types of fluctuations that seem to be due to infiltration of the drilling fluid into the formation during the construction of the monitoring well.

Shallow Monitoring Zone

Graphical presentation of the data collected from the shallow monitor zone is presented in Appendix E. The temperature data shows some fluctuation during about the first year and a half, from this point it appears to have stabilized at about 27 degrees C. The pH data shows s slight fluctuations from one analyses to the next, but stays within the range of 7.5 to 8.0. Conductivity data shows some fluctuations during the first year, after this time the values stabilized at about 6,000 umhos/cm. Chloride data shows some fluctuations from one sampling event to the next over the entire period, but no discernible trend of either increase or decrees can be seen in the data. The TDS data has the same look as the chloride data with no trend other than stabilization apparent. The ammonia data also shows some fluctuation from event to event with no increasing trend that can be seen from the data. Based on the total review of the data from the shallow monitoring zone there does not appear to be any change in the water quality of the shallow monitoring zone.

Deep Monitoring Zone

Graphical presentation of the data collected from the deep monitor zone is presented in Appendix F. The temperature data for the deep monitor zone has stayed in the range of 27 to 27.5 degrees C for the entire period of the data. During the first year the pH seemed to show an increase form about 7.25 to about 7.6 where it has remained stable. The conductivity shows an increase from about 22,000 umhos/cm to about 28,000 umhos/cm over the first 18 months, stabilizing at 28,000 mhos/cm for the rest of the monitoring period. The chloride data has been relatively stable at about 10,000 mg/l for the entire period. The TDS data shows fluctuation between sampling events, but overall does not indicate either an upward or downward trend. Over the entire period the ammonia data has hovered around 0.5 mg/l. Based on the total review of the data from the deep monitoring zone there does not appear to be any change in the water quality of the deep monitoring zone.

Conclusions

Based on the results of the temperature log, hydrostatic pressure test, radioactive tracer survey, television survey and review of the analytical data collected from the duel zone monitoring well there is no indication that the City of Pahokee injection well lacks mechanical integrity at this time.

Attn.: Mr. Robert Binger

Ref. : City of Pahokee Injection Well Plugging and Abandonment

COST ESTIMATE:

Dear Mr. Binger;

We have reviewed the information you sent regarding the City of Pahokee's 12 inch Injection Well

From this information we have developed the following estimate of costs to Plug and Abandon the subject well. Our estimate includes mobilizing all required equipment to the site and pumping a theoretical volume of cement. Wellhead disassembly, site preparation and restoration is to be performed by owner. Geophysical Logging if required will be at additional cost.

All work will be performed in accordance with applicable regulations of the Florida Department of Environmental Protection, South Florida Water Management and local authorities.

ESTIMATE TO PLUG & ABANDON INJECTION WELL \$ 70,934.<u>00</u>

TOTAL PROJECT ESTIMATE

\$ 70,934.00

Should we be able to provide any additional information, and /or clarification of anything contained herein please do not hesitate to call.

Bill Musselwhite

Vice President

To : Craig A. Smith & Associates

Attn.: Mr. Robert Binger

Ref.: City of Pahokee Injection Well Plugging and Abandonment

Cost Estimate Detail:

Dear Mr. Binger;

We are pleased to offer the following breakdown to accompany our Cost Estimate for the Plugging and Abandonment of the City of Pahokee Injection Well.

Our estimate was conditioned on the owner providing all wellhead disassembly, site preparation and restoration.

Our estimate is predicated on two basic factors. First, the theoretical volume of cement to be pumped, and second, a lump sum amount to cover Mobilization, Demobilization, Set-Up Charges, etc.

Shown below is the basic make up of our estimate.

INJECTION WELL

Cement 2,702 cubic feet

Cement Value 17.00 per cu. ft. Sub - Total \$ 45,934,00

Mob., Demob, \$ 25,000.00

TOTAL \$ 70,934.00

I trust the above information is sufficient to your purpose. Please contact me should I be able to be of further assistance.

Bill Musselwhite

Sincerely

Vice President

RE: City of Pahokee, Florida

This is to advise that the undersigned is the City Attorney for the City of Pahokee, Florida.

This is to further confirm that the City of Pahokee, Florida, is, in fact, a Florida "Municipality" created pursuant to general or special law authorized or recognized pursuant to s.2 or s.6, Article VIII of the State of Florida Constitution.

The City of Pahokee, Florida, as a Florida "Municipality" has the governmental, corporate, and proprietary powers to enable the City of Pahokee to conduct municipal government, perform municipal functions, and render municipal services and to exercise any power for municipal purposes except, when expressly prohibited by law as more specifically set forth in Chapter 166 of the Florida Statutes.

Specifically, the City of Pahokee meets the definition of a local government as defined in Chapter 218, Florida Statutes, including, but not limited to, Part V of Chapter 218, Florida Statutes, entitled "Financial Emergencies".

If you have any further questions regarding the City of Pahokee, Florida's status as a Florida "Municipality", please feel free to contact me at any time.

Very truly yours,

Michael√H./Stauder

ANALYTICAL REPORT

TESTED FOR:

Environmental Services of South

PROJECT:

Water Analysis

Florida

P.O. Box 10003 Riviera, Fl. 33419 Letter received 12/24/96

ATTENTION:

Mike Feidor

DATE:

January 3, 1997

OUR REPORT NUMBER: 385-6P235-0060

Attached, please find our analytical report for samples described on the Chain-of-Custody (C-O-C). Please note that our laboratory has assigned unique sample numbers to each of your samples as shown on the attached C-O-C. Please reference our report number and direct any questions on this report to the individual designated below or to one of our Customer Service Representatives.

HARBOR BRANCH ENVIRONMENTAL LABORATORY

Quality Control Project Narrative

Client:

Name: Environmental Services of South Florida

Project: Pahokee HPN # 63028

Samples were accepted by Harbor Branch Environmental Laboratory in accordance with documented sample acceptance procedures. Analytical results presented in this report have been reviewed for compliance with laboratory QA/QC plan. The QC parameters which were evaluated have been summarized below. Noncompliant items are noted.

• Laboratory Blank:

All analytes were below Method Detection Limits (MDL).

• Laboratory Control Sample:

Recoveries for analytes were within laboratory precision and

accuracy limits.

Matrix Spike/Matrix Spike

Duplicate:

Recoveries for analytes were within laboratory precision and

accuracy limits.

HARBOR BRANCH ENVIRONMENTAL LABORATORY

Quality Control Project Narrative

Client:

Name: Environmental Services of South Florida

Project: Pahokee HPN # 63035

Samples were accepted by Harbor Branch Environmental Laboratory in accordance with documented sample acceptance procedures. Analytical results presented in this report have been reviewed for compliance with laboratory QA/QC plan. The QC parameters which were evaluated have been summarized below. Non-compliant items are noted.

Laboratory Blank:

All analytes were below Method Detection Limits (MDL).

Laboratory Control Sample:

Recoveries for analytes were within laboratory precision

and accuracy limits.

Matrix Spike/Matrix Spike

Duplicate:

Recoveries for analytes were within laboratory precision

and accuracy limits.

Due to a spiking error, surrogate recoveries for the samples associated with HPN 62926 and associated quality control samples did not meet EPA Method 508 specified criteria. All spike recoveries in the matrix spike and matrix spike duplicate and laboratory control sample and control sample duplicate met precision and accuracy criteria. Additionally, a double blind performance evaluation sample showed acceptable recoveries, thereby concluding that results obtained for the quality control batch had accurate results.

Erik S. Penfield

Quality Assurance Manager
